Data Information

Get the data from : http://www.nyc.gov/html/tlc/html/about/trip_record_data.shtml

(http://www.nyc.gov/html/tlc/html/about/trip_record_data.shtml) (2016 data) The data used in the attached datasets were collected and provided to the NYC Taxi and Limousine Commission (TLC)

Information on taxis:

Yellow Taxi: Yellow Medallion Taxicabs

These are the famous NYC yellow taxis that provide transportation exclusively through street-hails. The number of taxicabs is limited by a finite number of medallions issued by the TLC. You access this mode of transportation by standing in the street and hailing an available taxi with your hand. The pickups are not pre-arranged.

For Hire Vehicles (FHV)

FHV transportation is accessed by a pre-arrangement with a dispatcher or limo company. These FHV's are not permitted to pick up passengers via street hails, as those rides are not considered pre-arranged.

Green Taxi: Street Hail Livery (SHL)

The SHL program will allow livery vehicle owners to license and outfit their vehicles with green borough taxi branding, meters, credit card machines, and ultimately the right to accept street hails in addition to pre-arranged rides.

Credits: Quora

Footnote:

In the given notebook we are considering only the yellow taxis for the time period between Jan - Mar 2015 & Jan - Mar 2016

Data Collection

We Have collected all yellow taxi trips data from jan-2015 to dec-2016(Will be using only 2015 data)

month.fare_amount.sum().visualize()
```

Out[98]:

Features in the dataset:

Field Name		Description
VendorID	1.	A code indicating the TPEP provider that provided the record. Creative Mobile Technologies VeriFone Inc.
	2.	
tpep_pickup_datetime		The date and time when the meter was engaged.
tpep_dropoff_datetime		The date and time when the meter was disengaged.
Passenger_count		The number of passengers in the vehicle. This is a driver-entered value.
Trip_distance		The elapsed trip distance in miles reported by the taxiometer.
Pickup_longitude		Longitude where the meter was engaged.
Pickup_latitude		Latitude where the meter was engaged.
RateCodeID		The final rate code in effect at the end of the trip.
	1.	Standard rate
	2.	JFK
	3.	Newark
	4.	Nassau or Westchester
	5.	Negotiated fare
Store_and_fwd_flag	6.	Group ride
		This flag indicates whether the trip record was held in vehicle memory before sending to the vendor, aka "store and forward," because the vehicle did not have a connection to the server. Y= store and forward trip N= not a store and forward trip
Dropoff_longitude		Longitude where the meter was disengaged.
Dropoff_latitude		Latitude where the meter was disengaged.
Payment_type		A numeric code signifying how the passenger paid for the trip.
	1.	Credit card
	2.	Cash
	3.	No charge
	4.	Dispute
	5.	Unknown
Fare_amount	6.	Voided trip
		The time-and-distance fare calculated by the meter.
Extra		Miscellaneous extras and surcharges. Currently, this only includes. the 0.50and1 rush hour and overnight charges.
MTA_tax		0.50 MTA tax that is automatically triggered based on the metered rate in use.
Improvement_surcharge		0.30 improvement surcharge assessed trips at the flag drop. the improvement surcharge began being levied in 2015.
Tip_amount		Tip amount – This field is automatically populated for credit card tips.Cash tips are not included.
Tolls_amount		Total amount of all tolls paid in trip.

Total_amount

The total amount charged to passengers. Does not include cash tips.

ML Problem Formulation

Time-series forecasting and Regression

- To find number of pickups, given location coordinates(latitude and longitude) and time, in the query region and surrounding regions.

To solve the above we would be using data collected in Jan - Mar 2015 to predict the pickups in Jan - Mar 2016.

Performance metrics

1. Mean Absolute percentage error.
2. Mean Squared error.

Data Cleaning

In this section we will be doing univariate analysis and removing outlier/illegitimate values which may be caused due to some error

In [3]:

```
#table below shows few datapoints along with all our features
month.head(5)
```

Out[3]:

	VendorID	tpep_pickup_datetime	tpep_dropoff_datetime	passenger_count	trip_distance	pickup
0	2	2015-01-15 19:05:39	2015-01-15 19:23:42	1	1.59	
1	1	2015-01-10 20:33:38	2015-01-10 20:53:28	1	3.30	
2	1	2015-01-10 20:33:38	2015-01-10 20:43:41	1	1.80	
3	1	2015-01-10 20:33:39	2015-01-10 20:35:31	1	0.50	
4	1	2015-01-10 20:33:39	2015-01-10 20:52:58	1	3.00	

1. Pickup Latitude and Pickup Longitude

It is inferred from the source <https://www.flickr.com/places/info/2459115> (https://www.flickr.com/places/info/2459115) that New York is bounded by the location coordinates(lat,long) - (40.5774, -74.15) & (40.9176,-73.7004) so hence any coordinates not within these coordinates are not considered by us as we are only concerned with pickups which originate within New York.

In [4]:

```
# Plotting pickup coordinates which are outside the bounding box of New-York
# we will collect all the points outside the bounding box of newyork city to outlier_location
outlier_locations = month[((month.pickup_longitude <= -74.15) | (month.pickup_latitude <= 40.5774) |
                           (month.pickup_longitude >= -73.7004) | (month.pickup_latitude >= 40.9176))]

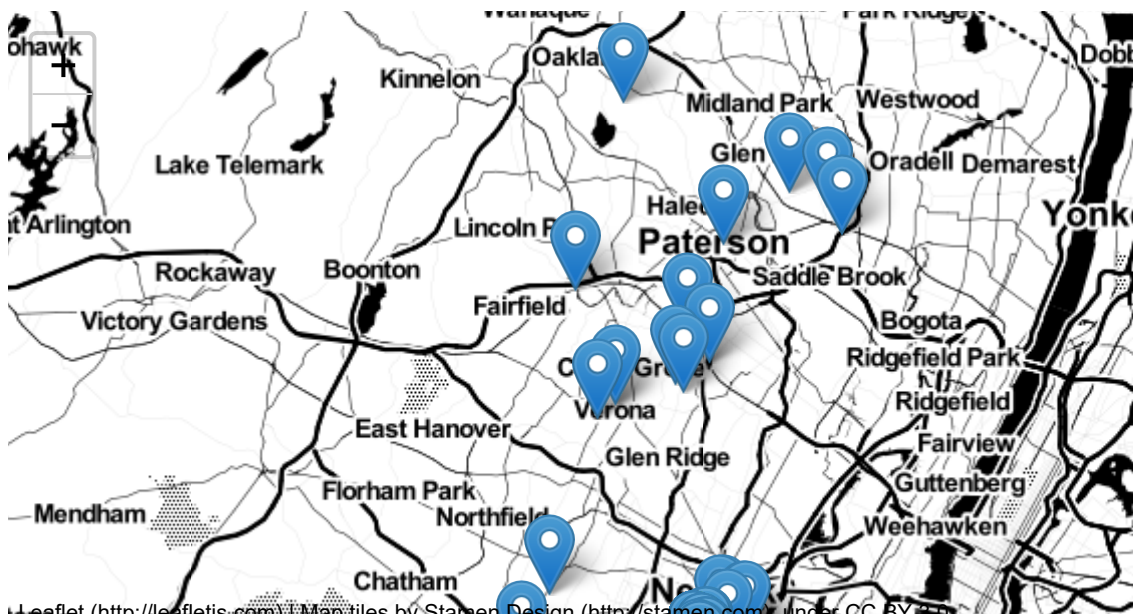

# creating a map with the a base location
# read more about the folium here: http://folium.readthedocs.io/en/latest/quickstart.html

# note: you dont need to remember any of these, you dont need indepth knowledge on these m

map_osm = folium.Map(location=[40.734695, -73.990372], tiles='Stamen Toner')

# we will spot only first 100 outliers on the map, plotting all the outliers will take more
sample_locations = outlier_locations.head(10000)
for i,j in sample_locations.iterrows():
    if int(j['pickup_latitude']) != 0:
        folium.Marker(list((j['pickup_latitude'],j['pickup_longitude']))).add_to(map_osm)
map_osm
```

Out[4]:

Observation:- As you can see above that there are some points just outside the boundary but there are a few that are in either South america, Mexico or Canada

2. Dropoff Latitude & Dropoff Longitude

It is inferred from the source <https://www.flickr.com/places/info/2459115> (<https://www.flickr.com/places/info/2459115>) that New York is bounded by the location coordinates(lat,long) - (40.5774, -74.15) & (40.9176,-73.7004) so hence any coordinates not within these coordinates are not considered by us as we are only concerned with dropoffs which are within New York.

```
# Plotting dropoff coordinates which are outside the bounding box of New-York
# we will collect all the points outside the bounding box of newyork city to outlier_locations
outlier_locations = month[((month.dropoff_longitude <= -74.15) | (month.dropoff_latitude <=
                           (month.dropoff_longitude >= -73.7004) | (month.dropoff_latitude >= 40.91

# creating a map with the a base location
# read more about the folium here: http://folium.readthedocs.io/en/latest/quickstart.html

# note: you dont need to remember any of these, you dont need indepth knowledge on these m

map_osm = folium.Map(location=[40.734695, -73.990372], tiles='Stamen Toner')

# we will spot only first 100 outliers on the map, plotting all the outliers will take more
sample_locations = outlier_locations.head(10000)
for i,j in sample_locations.iterrows():
    if int(j['pickup_latitude']) != 0:
        folium.Marker(list((j['dropoff_latitude'],j['dropoff_longitude']))).add_to(map_osm)
map_osm
```

3. Trip Durations:

```

Observation:- As even the 99.9th percentile value doesn't look like an outlier, as there is not much difference between the 99.8th percentile and 99.9th percentile, we move on to do graphical analysis

In [34]:

```
#below plot shows us the fare values(sorted) to find a sharp increase to remove those value  
# plot the fare amount excluding last two values in sorted data  
plt.plot(var[:-2])  
plt.show()
```

Figure 10

In [35]:

```
# a very sharp increase in fare values can be seen  
# plotting last three total fare values, and we can observe there is share increase in the  
plt.plot(var[-3:])  
plt.show()
```

Figure 11

In [36]:

```
#now looking at values not including the last two points we again find a drastic increase a  
# we plot last 50 values excluding last two values  
plt.plot(var[-50:-2])  
plt.show()
```

Figure 12

Inference:

- The main objective was to find a optimal min. distance(Which roughly estimates to the radius of a cluster) between the clusters which we got was 40

In [40]:

```
# if check for the 50 clusters you can observe that there are two clusters with only 0.3 mi
# so we choose 40 clusters for solve the further problem
```

```
# Getting 40 clusters using the kmeans
```

```
kmeans = MiniBatchKMeans(n_clusters=40, batch_size=10000, random_state=0).fit(coords)
frame_with_durations_outliers_removed['pickup_cluster'] = kmeans.predict(frame_with_durations_outliers_removed['pickup_cluster'])
```

Plotting the cluster centers:

In [41]:

```
# Plotting the cluster centers on OSM
```

```
cluster_centers = kmeans.cluster_centers_
```

```
cluster_len = len(cluster_centers)
```

```
map_osm = folium.Map(location=[40.734695, -73.990372], tiles='Stamen Toner')
```

```
for i in range(cluster_len):
```

```
    folium.Marker(list((cluster_centers[i][0], cluster_centers[i][1])), popup=(str(cluster_centers[i][0], cluster_centers[i][1])), icon=folium.Icon(color='blue', icon='location'))
```

```
map_osm
```

Out[41]:

Plotting the clusters:

In [42]:

```

#Visualising the clusters on a map
def plot_clusters(frame):
    city_long_border = (-74.03, -73.75)
    city_lat_border = (40.63, 40.85)

```

there are two ways to fill up these values

- Fill the missing value with 0's
- Fill the missing values with the avg values
 - Case 1:(values missing at the start)
 - Ex1: __ _ x => ceil(x/4), ceil(x/4), ceil(x/4), ceil(x/4)
 - Ex2: __ _ x => ceil(x/3), ceil(x/3), ceil(x/3)
 - Case 2:(values missing in middle)
 - Ex1: x __ _ y => ceil((x+y)/4), ceil((x+y)/4), ceil((x+y)/4), ceil((x+y)/4)
 - Ex2: x __ _ y => ceil((x+y)/5), ceil((x+y)/5), ceil((x+y)/5), ceil((x+y)/5), ceil((x+y)/5)
 - Case 3:(values missing at the end)
 - Ex1: x __ _ => ceil(x/4), ceil(x/4), ceil(x/4), ceil(x/4)
 - Ex2: x _ => ceil(x/2), ceil(x/2)

```
# why we choose, these methods and which method is used for which data?

# Ans: consider we have data of some month in 2015 jan 1st, 10 _ _ 20, i.e there are 10 p
# 10st 10min intravel, 0 pickups happened in 2nd 10mins intravel, 0 pickups happened in 3rd
# and 20 pickups happened in 4th 10min intravel.
# in fill_missing method we replace these values like 10, 0, 0, 20
# where as in smoothing method we replace these values as 6,6,6,6,6, if you can check the n
# that are happened in the first 40min are same in both cases, but if you can observe that
# when you are using smoothing we are looking at the future number of pickups which might

# so we use smoothing for jan 2015th data since it acts as our training data
# and we use simple fill_missing method for 2016th data.
```

```

Modelling: Baseline Models

Now we get into modelling in order to forecast the pickup densities for the months of Jan, Feb and March of 2016 for which we are using multiple models with two variations

1. Using Ratios of the 2016 data to the 2015 data i.e $R_t = P_t^{2016}/P_t^{2015}$
2. Using Previous known values of the 2016 data itself to predict the future values

Simple Moving Averages

The First Model used is the Moving Averages Model which uses the previous n values in order to predict the next value

Using Ratio Values - $R_t = (R_{t-1} + R_{t-2} + R_{t-3} \dots R_{t-n})/n$

In [60]:

```
def MA_R_Predictions(ratios,month):
    predicted_ratio=(ratios['Ratios'].values)[0]
    error=[]
    predicted_values=[]
    window_size=3
    predicted_ratio_values=[]
    for i in range(0,4464*40):
        if i%4464==0:
            predicted_ratio_values.append(0)
            predicted_values.append(0)
            error.append(0)
            continue
        predicted_ratio_values.append(predicted_ratio)
        predicted_values.append(int(((ratios['Given'].values)[i])*predicted_ratio))
        error.append(abs((math.pow(int(((ratios['Given'].values)[i])*predicted_ratio)-(ratios['Given'].values)[i])))
        if i+1>=window_size:
            predicted_ratio=sum((ratios['Ratios'].values)[(i+1)-window_size:(i+1)])/window_size
        else:
            predicted_ratio=sum((ratios['Ratios'].values)[0:(i+1)])/(i+1)

    ratios['MA_R_Predicted'] = predicted_values
    ratios['MA_R_Error'] = error
    mape_err = (sum(error)/len(error))/(sum(ratios['Prediction'].values)/len(ratios['Prediction'].values))
    mse_err = sum([e**2 for e in error])/len(error)
    return ratios,mape_err,mse_err
```

For the above the Hyperparameter is the window-size (n) which is tuned manually and it is found that the window-size of 3 is optimal for getting the best results using Moving Averages using previous Ratio values therefore we get $R_t = (R_{t-1} + R_{t-2} + R_{t-3})/3$

Next we use the Moving averages of the 2016 values itself to predict the future value using

$$P_t = (P_{t-1} + P_{t-2} + P_{t-3} \dots P_{t-n})/n$$

In [61]:

```
def MA_P_Predictions(ratios,month):
    predicted_value=(ratios['Prediction'].values)[0]
    error=[]
    predicted_values=[]
    window_size=1
    predicted_ratio_values=[]
    for i in range(0,4464*40):
        predicted_values.append(predicted_value)
        error.append(abs((math.pow(predicted_value-(ratios['Prediction'].values)[i],1))))
        if i+1>=window_size:
            predicted_value=int(sum((ratios['Prediction'].values)[(i+1)-window_size:(i+1)]))
        else:
            predicted_value=int(sum((ratios['Prediction'].values)[0:(i+1)])/(i+1))

    ratios['MA_P_Predicted'] = predicted_values
    ratios['MA_P_Error'] = error
    mape_err = (sum(error)/len(error))/(sum(ratios['Prediction'].values)/len(ratios['Prediction']))
    mse_err = sum([e**2 for e in error])/len(error)
    return ratios,mape_err,mse_err
```

For the above the Hyperparameter is the window-size (n) which is tuned manually and it is found that the window-size of 1 is optimal for getting the best results using Moving Averages using previous 2016 values therefore we get $P_t = P_{t-1}$

Weighted Moving Averages

The Moving Averages Model used gave equal importance to all the values in the window used, but we know intuitively that the future is more likely to be similar to the latest values and less similar to the older values. Weighted Averages converts this analogy into a mathematical relationship giving the highest weight while computing the averages to the latest previous value and decreasing weights to the subsequent older ones

Weighted Moving Averages using Ratio Values -

$$R_t = (N * R_{t-1} + (N - 1) * R_{t-2} + (N - 2) * R_{t-3} \dots 1 * R_{t-n}) / (N * (N + 1) / 2)$$

In [62]:

```
def WA_R_Predictions(ratios,month):
    predicted_ratio=(ratios['Ratios'].values)[0]
    alpha=0.5
    error=[]
    predicted_values=[]
    window_size=5
    predicted_ratio_values=[]
    for i in range(0,4464*40):
        if i%4464==0:
            predicted_ratio_values.append(0)
            predicted_values.append(0)

```

For the above the Hyperparameter is the window-size (n) which is tuned manually and it is found that the window-size of 2 is optimal for getting the best results using Weighted Moving Averages using previous 2016 values therefore we get $P_t = (2 * P_{t-1} + P_{t-2})/3$

Exponential Weighted Moving Averages

https://en.wikipedia.org/wiki/Moving_average#Exponential_moving_average

(https://en.wikipedia.org/wiki/Moving_average#Exponential_moving_average) Through weighted averaged we have satisfied the analogy of giving higher weights to the latest value and decreasing weights to the subsequent ones but we still do not know which is the correct weighting scheme as there are infinitely many possibilities in which we can assign weights in a non-increasing order and tune the the hyperparameter window-size. To simplify this process we use Exponential Moving Averages which is a more logical way towards assigning weights and at the same time also using an optimal window-size.

In exponential moving averages we use a single hyperparameter alpha (α) which is a value between 0 & 1 and based on the value of the hyperparameter alpha the weights and the window sizes are configured.

For eg. If $\alpha = 0.9$ then the number of days on which the value of the current iteration is based is~

$1/(1 - \alpha) = 10$ i.e. we consider values 10 days prior before we predict the value for the current iteration. Also the weights are assigned using $2/(N + 1) = 0.18$, where N = number of prior values being considered, hence from this it is implied that the first or latest value is assigned a weight of 0.18 which keeps exponentially decreasing for the subsequent values.

$$R'_t = \alpha * R_{t-1} + (1 - \alpha) * R'_{t-1}$$

In [64]:

```
def EA_R1_Predictions(ratios,month):

Comparison between baseline models

We have chosen our error metric for comparison between models as **MAPE (Mean Absolute Percentage Error)** so that we can know that on an average how good is our model with predictions and **MSE (Mean Squared Error)** is also used so that we have a clearer understanding as to how well our forecasting model performs with outliers so that we make sure that there is not much of a error margin between our prediction and the actual value

In [67]:

```
print ("Error Metric Matrix (Forecasting Methods) - MAPE & MSE")
print ("-----")
